VECTORS

Scalars and Vectors:

Scalar:

That physical quantity which needs magnitude as well as proper unit and having direction is called scalar.

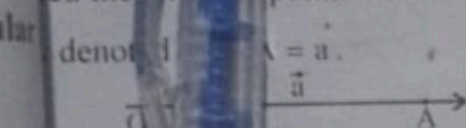

Examples: Mass, speed, volume, length etc.

Vector: That physical quantity which needs magnitude, proper direction and it is called vector.

Examples: Velocity, acceleration, force etc.

Geometrical Representation of a Vector:

A vector is represented by an arrow $\vec{OA}$. Initially "O" is called the initial point or origin and head "A" is called the terminal point. Vector is generally denoted by $\vec{a}$.

Vectors are denoted by $\vec{a}, \vec{b}, \vec{c}$ etc. The standard notation used for vectors is $\vec{a}, \vec{b}, \vec{c}$.

Fundamentals of a vector

Magnitude of a Vector:

A real number which shows the length of

vector $\vec{a}$ is called the magnitude of $\vec{a}$.

denoted by $|\vec{a}|$ or $|\vec{OA}|$ the magnitude of $\vec{a}$.

Unit Vector:

A vector whose magnitude is one and it is used to represent the direction is called unit vector. It is written as $\hat{a}$.

here $\hat{a}$ is unit vector i.e. unit

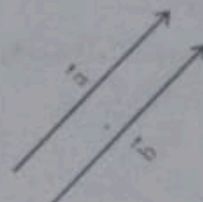

vector in a direction

= $\frac{\text{vector in that direction}}{\text{modulus of the vector}}$

$\hat{i}, \hat{j}, \hat{k}$ are the unit vectors for representing x, y, z direction.

(iii) Equal Vectors:

The two vectors $\vec{a}$ and $\vec{b}$ are said to be equal if they have same magnitude and same direction i.e. $\vec{a} = \vec{b}$.

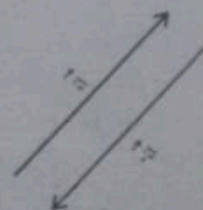

(iv) Null or Zero Vector:

That vector whose magnitude is zero and has arbitrary direction is called null vector. It is denoted as $\vec{0}$.

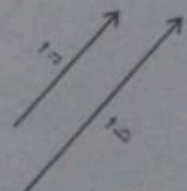

(v) Negative of a Vector:

That vector which has same magnitude but opposite direction to the given vector is called negative of a vector.

(vi) Parallel Vectors:

If $\vec{a} = \lambda \vec{b}$ or $\vec{b} = \lambda \vec{a}$ where λ is a scalar, then $\vec{a}$ and $\vec{b}$ are called parallel vectors.
